With the facilities offered by the various scientific libraries at Harvard University, the Massachusetts Institute of Technology, and other libraries in Boston, it has been possible to collect nearly all the data relating to the subject. For the work before 1860 Professor Storer's work has been found invaluable.

The method pursued has been to form a preliminary list of compounds with more or less data by consulting the two most complete works on inorganic chemistry—Gmelin-Kraut's "*Handbuch der anorganischen Chemie*" and Graham-Otto-Michaelis's "*Lehrbuch*." These statements have been verified and elaborated by consulting the original memoirs in all the periodicals devoted to chemical literature which were obtainable. The "*Jahresbericht der Chemie*" also has been used extensively in tracing references, but the original memoirs have always been consulted and references given to them when possible.

It has been found impracticable to draw any distinction as to reliability between the various data given by different observers. It was manifestly impossible to attempt to verify experimentally the statements of those who have carried on the researches, for the most assiduous labor of many could only cover a small portion of the attested facts. Therefore, even when two statements are directly contradictory, both have been given with the authority for each. The only exception to this has been made when more recent discoveries have shown beyond any reasonable doubt the falsity of previous work. In this way some of the older manifestly inaccurate work has been omitted. In a majority of cases the more recent work may be considered to be the more accurate, but this is not the invariable rule. A Synchronistic Table of the more common periodicals is given in the Appendix, whereby it is easy to determine the date of the publication of a research to which reference is made.

It may be objected by the practical chemist that most of the work previous to 1850 might well have been omitted, but a great deal of this work possesses at least a historical value, and often furnishes facts which have not since been verified. Much of the earlier work, when obviously of less importance, has been printed in smaller type.

The aim has been to include in this volume all analyzed inorganic substances, that is, all substances which do not contain carbon, but exception has been made in the case of  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{CS}_2$ , the carbonates, cyanides, ferro-cyanides, etc., which are here included.

The work has been brought up to March, 1894, when this volume went to press, and the results of researches published since that time are not included in the present edition.

It is hoped that this book will fill to some extent the want that has been felt by chemists for a compilation of this nature. While it has been attempted to make the book as free from errors as possible, nevertheless it is naturally impossible to avoid many mistakes, and the compiler will be very grateful to those who may call his attention to any errors or omissions.

## PREFACE TO SECOND EDITION

DURING the twenty-five years which have elapsed since the publication of the first edition of this dictionary, a very large amount of work has been published in chemical periodicals, containing data concerning the solubility of inorganic chemical compounds. As it was impossible for the compiler of the first edition to devote the time necessary for the collecting of the published data, it was necessary to employ assistance, and Dr. Dorothy A. Hahn, Professor of Chemistry, Mt. Holyoke College, was engaged for this work. Dr. Hahn has collected the larger part of the material in this book, which work in spite of its arduous and tedious nature, she has performed in a most painstaking manner.

The compilation and arrangement of the data collected by Dr. Hahn, which devolved upon the original author, took much time. This, together with difficulties in printing, caused by the general conditions after the war, has delayed the publication until the present year, although the work was begun in 1916, and it has only been brought up to January 1st of that year.

Since the publication of the first edition of this work, Dr. Atherton Seidell has brought out two editions of his book, entitled "Solubilities of Inorganic and Organic Substances," which covers quite a different field, as he considers only quantitative data and those only for the commoner substances. Dr. Seidell has followed the plan in most cases where there are several available solubility determinations of a substance, of selecting and averaging the more reliable results, and embodying them in tables. Although this undoubtedly facilitates ready reference, it has seemed better to adhere to the original plan of the first edition, and to publish all the data in the form of the original authorities with references and dates, so that the user may be at liberty to use his own judgment in selection. Some few of the tables arranged by Dr. Seidell, however, have seemed to possess decided advantages over any other published data and they have been incorporated in the present volume. It is desired also to acknowledge indebtedness to Dr. Seidell's work for certain other tables where the original sources were not available to the present compilers.

The same plan and arrangement used in the first edition has been followed with certain elaboration, however, of the arrangement of data on the solubility of two or more salts in a solvent, which is explained in the Explanatory Preface.

Data published since the first edition on the cobalt and chromium ammonium compounds and those of the platinum group have been omitted, as it seemed that solubility data on those compounds possessed very little general interest.

As stated in the preface of the first edition, while every possible attempt has been made to avoid errors, it is manifestly impossible to avoid many mistakes in a work of this nature, and the compiler will be glad to have his attention called to any errors or omissions.

WILMINGTON, Del., Jan., 1921.

## EXPLANATORY PREFACE

IN order to reduce this volume to a convenient size the subject-matter has been abbreviated and condensed as far as seemed compatible with clearness; but it has been the aim not to use any abbreviations which are not at once intelligible without consulting the explanatory table. The more common chemical formulæ have been universally used, thereby saving a large amount of space without detracting from ready intelligibility to chemists.

The solubility of the substance in water is first given, the data being arranged chronologically in the longer articles. Then follow the specific gravities of the aqueous solutions, and also any data obtainable regarding their boiling-points; other physical data concerning solutions are not included. Following this is the solubility of the substance in other solvents—first the inorganic acids, then alkali and salt solutions, and finally organic substances.

Owing to the great increase of data, published during the last twenty years, on the simultaneous solubility of two or more salts in a given solvent, it has been found necessary to plan some arrangement, whereby such data can easily be found, and the plan adopted is as follows: The data for the solubility of two salts in a solvent is placed under the salt which comes first according to the alphabetical arrangement in this dictionary, and the order of the data on various salts under the same heading follows the alphabetical order of the salts considered. Thus the data on the solubility of  $\text{NH}_4\text{Cl} + \text{BaCl}_2$ ,  $\text{NH}_4\text{Cl} + \text{CuCl}_2$ , and  $\text{NH}_4\text{Cl} + \text{PbCl}_2$ , and  $\text{NH}_4\text{Cl} + (\text{NH}_4)_2\text{SO}_4$  are placed under Ammonium Chloride and arranged in the given order. Certain exceptions have been made to this rule, where the data directly concerns the solubility of a salt in a solution of another salt, in which case, it is placed under the former. Numerous cross references, however, are given, which it is hoped will avoid confusion.

In many cases no definite distinction can be drawn between the phenomena of solution and decomposition. At present the theory of solution is in a confused state, and until what really takes place when a substance dissolves is thoroughly understood no distinct line can be drawn. The whole subject is unsettled at the present time; for while many chemists believe in the so-called "dissociation" theory, yet the "hydrate" theory is not without its supporters. It is not my intention to discuss the theoretical side of the question, which has been so well treated in many recent works. It is, however, obvious that the phenomena are essentially different, when, for example, sodium carbonate is dissolved in water, in which case the original salt is deposited on evaporation, and when iron is dissolved in sulphuric acid, and the solution deposits a sulphate of iron. Yet it is still the custom to speak of iron as soluble in sulphuric acid, although it would be much more accurate to say that the sulphuric acid was decomposed by the iron. It has thus been found impracticable to draw a sharp line between solu-

tion and decomposition, and the term "soluble" has in general been used where a solution of some sort is formed by the action of the solvent.

The matter of alphabetical arrangement of chemical compounds, in the present somewhat confused state of chemical nomenclature, has been a difficult question to decide. The plan followed has been practically that of the standard Dictionaries of Chemistry, whereby the compounds of metals with one of the non-metallic elements have been classified under the metals, while the salts of the other acids (the oxygen acids so called and some few others) have been arranged alphabetically under the acids. Thus barium chloride is found under barium, while barium chlorate is found under chloric acid. No exception has been made in the case of the rare metals, as is usually the custom in Dictionaries of Chemistry. Double salts are to be found under the word which comes first alphabetically; thus, "common alum," potassium aluminum sulphate, is found under aluminum sulphate as aluminum potassium sulphate (under sulphuric acid), but ammonia chrome alum is found under ammonium sulphate as ammonium chromium sulphate. In the same way the double sulphate and chromate of potassium is found under potassium chromate (chromic acid), and not under potassium sulphate (sulphuric acid). The double chloride of ammonium and magnesium is found under ammonium chloride (ammonium), while the double chloride of potassium and magnesium is found under magnesium chloride (magnesium). An exception is made, however, in the case of double compounds of salts of oxygen acids with salts containing a single non-metallic element, in which case they are always found under the oxygen acid. Thus the double sulphate and chloride of lead,  $\text{PbSO}_4$ ,  $\text{PbCl}_2$ , is found under lead sulphate (sulphuric acid), and not under lead chloride (lead).

The above method in some cases widely separates analogous compounds, but it was found to be the only practical way to a strictly alphabetical arrangement, which is ~~so~~ necessary in a book containing so many very short articles.

The ammonia addition-products furnished another difficulty. While their nature is more or less definitely understood in the cobalt, platinum, etc., compounds, and a definite nomenclature is in general use, there is an absolute lack of anything of the kind in the less definite compounds. It is good usage to speak of cuprammonium compounds, but how shall we designate the analogous cadmium compounds? "Cadmammonium" has not yet received the sanction of chemists, and  $\text{AlCl}_3$ ,  $\text{NH}_3$  is a still worse case for naming. I have, therefore, not attempted to name these compounds, but classified them all under the salts to which the ammonia is added, affixing the word ammonia, thus: aluminum chloride ammonia, cadmium chloride ammonia, and also cupric chloride ammonia for the salt now almost universally known as cuprammonium chloride.

The ammonia compounds of cobalt, chromium, mercury, and the platinum metals are arranged alphabetically according to their universally accepted names, a list of which is given under each of those elements.

It has further been necessary to settle arbitrarily the question whether a substance should be considered as a double salt or a salt of a compound acid con-

### INORGANIC

#### Actinium emanation.

Solubility coefficient of actinium emanation in  $H_2O$  at room temp. is 2.

If the solubility of actinium emanation in  $H_2O$  is made = 1, the relative solubility of the emanation in sat.  $KCl + Aq = 0.9$ ; in conc.  $H_2SO_4 = 0.95$ ; in ethyl alcohol = 1.1; in amyl alcohol = 1.6; in benzaldehyde = 1.7; in benzene = 1.8; in toluene = 1.8; in petroleum = 1.9; in  $CS_2 = 2.1$  at  $18^\circ$ .

#### Aluminum, Al.

Less easily attacked than ordinary metals (iron, copper, lead, zinc, tin) by air, H<sub>2</sub>O, wine, beer, coffee, milk, oil, butter, fats, etc. Vinegar dissolves 0.349 g. from a sq. decimetre in 4 months, and 5 % NaCl+Aq. only 0.045 g. in the same time. (Ballaud, C. R. 114. 1536.)

The action of various substances contained in foods and drinks on compact Al as it occurs in utensils is very slight. Hard or soft water, whether cold or hot, showed no action in 8 days; 1 % solutions of tartaric, tannic, and acetic acids had no action in same time, also 5 % boric, carbolic, and salicylic acids. 4 % and 10 % acetic acid dissolved only 0.4 mg. of Al, while 10 % acetic acid dissolved 2.1 mg. from a roughened piece of Al foil in 8 days. 1 % soda solution dissolved 15 mg. in 8 days. (Rupp, Dingl. 283. 119.)

Similar results were obtained by Arche. (Dingl. 284. 255.)

Liquids which are ordinarily contained in foods and drinks do not attack sheet Al except in a very small degree. The following losses in weight in mg. by the action of the given liquids on 100 sq. centimetres sheet aluminum for 6 days were obtained:

(Lunge, C.N. 65. 110.)

Sv. The apparent solubility of this metal in H<sub>2</sub>O is due to the presence of minute quantities of Na. Absolutely pure Al does not lose any weight to H<sub>2</sub>O and the H<sub>2</sub>O remains perfectly clear. Also dil. acids remain perfectly clear. (Moissan, C. R. 1895, 121. 794-98; C. C. 1896, I. 193.)

Te. Not attacked by HNO<sub>3</sub> + Aq even when conc. and boiling (Wöhler); easily sol. in dil. H<sub>2</sub>SO<sub>4</sub>, or HNO<sub>3</sub> + Aq in vacuo (Weeren, B. 24. 1798); slowly sol. in 27 % HNO<sub>3</sub> + Aq, 100 cem. HNO<sub>3</sub> + Aq requiring 2 months to dissolve 2 g. W. Slowly attacked by HNO<sub>3</sub> + Aq (20-25 %) at 25-30°. (Deventer, Chem. Weekbl. 1907, 4. 69.)

Z. Dil. HNO<sub>3</sub> or H<sub>2</sub>SO<sub>4</sub> does not attack Al on account of formation of layer of gas. Action is increased by vacuum. Solutions of metallic chlorides, the metal of which is insol. and attaches itself to the Al (Pt, Au, Cu, Hg) increase the solubility, but when metal is soluble in the acid (Fe, Zn, etc.), there is no increase of solubility. (Ditte, C. R. 1890, 110. 573.)

Z. Violently attacked by dil. or conc. H<sub>2</sub>PO<sub>4</sub> + Aq. (Winteler.)

Z. Not attacked by solution of HCl in liquid HCN. (Kahlenberg, J. phys. Chem. 1902, 6. 662.)

Z. Very easily sol. in conc. or dil. KOH, or NaOH + Aq. Slowly attacked by NH<sub>4</sub>OH +

Aq (Wöhler); sol. in BaO<sub>2</sub>H<sub>2</sub> + Aq (Beckmann, J. pr. (2) 26. 385); slowly sol. in CaO<sub>2</sub>H + Aq.

Aq. Sol. in excess of 10 % KOH + Aq and in NaOH and LiOH + Aq; sol. in hot conc. Ba(OH)<sub>2</sub>, Sr(OH)<sub>2</sub>, and Ca(OH)<sub>2</sub> + Aq. (Aller, Am. Ch. J. 1900, 24. 304-331.)

Attacked by hot conc. NH<sub>4</sub>OH + Aq (Smith, J. Soc. Chem. Ind. 1904, 23. 475.)

Sl. attacked by sulphates, or nitrates + Aq but all chlorides, bromides, and iodides, except those of the alkalis and alkaline earths, even AlCl<sub>3</sub> + Aq, dissolve the metal. Insol. in alum, or in NaCl + Aq, but sol. in alum-NaCl + Aq. (Tissier, C. R. 41. 362); sol. in NaCl + Aq (Deville, A. ch. (3) 43. 14); so in neutral FeCl<sub>3</sub> + Aq in vacuo. (Weeren, B. 24. 1798.) Violently attacked by CuCl<sub>2</sub> + Aq. (Tommasi, Bull. Soc. (2) 37. 443.)

Rapidly sol. in K<sub>2</sub>S<sub>2</sub>O<sub>8</sub> + Aq, more slowly in (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub>O<sub>8</sub> + Aq. (Levi, Gazz. ch. i. 1908, 38. (1) 583.)

Attacked by (NH<sub>4</sub>)<sub>3</sub>PO<sub>4</sub> + Aq. Sl. attacked by NaNO<sub>2</sub> + Aq or KNO<sub>3</sub> + Aq at 100° (Smith, J. Soc. Chem. Ind. 1904, 23. 475.)

Not affected by NH<sub>4</sub>NO<sub>3</sub> + Aq. (Hodgkinson, C. N. 1904, 90. 142.)

Attacked by POCl<sub>3</sub> at 100°. (Renitzer, F. 13. 845.)

Attacked by NOCl. (Sudborough, Chem. Soc. 1891, 59. 659.)

92 % alcohol attacks Al less than H<sub>2</sub>O. Pur Al is attacked less than commercial. (Hugouenq, J. Pharm. 1895, (6) 1. 537.)

Sol. in organic acids containing chlorides (Smith, J. Soc. Chem. Ind. 1904, 23. 475.)

Acetic, tartaric and citric acids attack Al only at first. Metal is covered by layer of hydroxide but on addition of haloid salts gradual solution ensues. (Ditte, C. R. 1890, 127. 919.)

Not attacked by sugar + Aq. (Klein, C. F. 102. 1170.)

**Aluminum arsenide.**

Decomp. by H<sub>2</sub>O with evolution of AsH<sub>3</sub> (Wöhler, Pogg. 11. 160.)

**Aluminum borocarbide, Al<sub>3</sub>C<sub>2</sub>B<sub>4</sub>s.**

Insol. in H<sub>2</sub>O, HCl + Aq, H<sub>2</sub>SO<sub>4</sub> + Aq, (

KOH + Aq; slowly sol. in hot conc.  $\text{HNO}_3$  + Aq. (Hampe, l. c.)

Min. *Bauxite*.

**Soluble modifications—(a) Meta-aluminum hydroxide From basic Al acetate.** Sol. in  $\text{H}_2\text{O}$  and more readily in  $\text{HC}_2\text{H}_3\text{O}_2$ . The aqueous solution is coagulated by traces of alkalies, many acids, and salts, while other acids and salts have no effect. Thus, 1 pt.  $\text{H}_2\text{SO}_4$  in 1000 pts.  $\text{H}_2\text{O}$ , added to 7000 pts. of above solution containing 20 pts.  $\text{Al}_2\text{O}_3$ , converts the liquid into a nearly solid mass. Citric, tartaric, oxalic, chromic, molybdic, racemic, suberic, salicylic, benzoic, gallic, lactic, cinnamic, butyric, valeric, camphoric, picric, uric, meconic, comenic, and hemipinic acids act in the same way.  $\text{HCl}$  and  $\text{HNO}_3$  have far less action, 600 mols. being necessary to produce the same effect as 1 mol.  $\text{H}_2\text{SO}_4$ , while acetic, formic, boric, arsenious, pyro-

meconic, and opianic acids do not coagulate the solution, except when moderately conc. 1 pt.  $\text{KOH}$  in 1000 pts.  $\text{H}_2\text{O}$  coagulates 9000 pts. of the solution.  $\text{NaOH}$ ,  $\text{NH}_4\text{OH}$ , and  $\text{Ca}(\text{OH})_2$  have the same effect.

The solution is not coagulated by acetates, unless added in large quantity, and even then the ppt. is redissolved when treated with  $\text{H}_2\text{O}$ . Nitrates and chlorides coagulate with difficulty;  $\text{Na}_2\text{SO}_4$ ,  $\text{MgSO}_4$ , and  $\text{CaSO}_4 + \text{Aq.}$  however, have as strong an action as a liquid containing the same amount of  $\text{H}_2\text{SO}_4$ . A teaspoonful of the solution introduced into the mouth solidifies at once from the action of the saliva. The ppt. formed by acids is not sol. in an excess of the acid, but by the long continued action of conc.  $\text{H}_2\text{SO}_4$ , especially if hot, the ppt. is dissolved; boiling conc.  $\text{HCl} + \text{Aq.}$  also dissolves it, but less readily than  $\text{H}_2\text{SO}_4$ . The ppt. is sol. in boiling conc.  $\text{KOH} + \text{Aq.}$  The residue, when the solution is evaporated at  $100^\circ$ , has composition  $\text{Al}_2\text{O}_3, 2\text{H}_2\text{O}$ , and is insol. in acids. (Crum, Chem. Soc. 6. 225.)

(b) *By Dialysis*. Sol. in  $\text{H}_2\text{O}$ , from which it is separated by extremely small amounts of various substances, as acids, ammonia, salts (especially  $\text{K}_2\text{SO}_4$ ), caramel, etc. An excess of acid dissolves the coagulum. If the solution contains 0.5%  $\text{Al}_2\text{O}_3$  or less, it may be boiled without change, but the hydroxide separates out suddenly when it is reduced to  $\frac{1}{2}$  its vol., and even very dil. solutions gelatinise spontaneously in a few days. The solution is not coagulated by alcohol or sugar. (Graham, A. 121. 41.)

$\text{Al}_2\text{O}_3, 3\text{H}_2\text{O} = \text{Al}(\text{OH})_3$ . **Crystallised.** Difficultly sol. in acids and alkalies. (Cossa, N. Cim. (2) 3. 228.) Insol. in boiling  $\text{HCl} + \text{Aq.}$  (Wöhler, A. 113. 249.) Sl. sol. in  $\text{KOH} + \text{Aq.}$ ; nearly insol. in cold  $\text{H}_2\text{SO}_4$ ,  $\text{HCl}$ ,  $\text{HNO}_3 + \text{Aq.}$ ; very slowly sol. in hot  $\text{HCl} + \text{Aq.}$ , more readily in hot  $\text{H}_2\text{SO}_4$ . (v. Bonsdorff, Pogg. 27. 275.)

$\alpha$ -modification. Unstable. Changes into  $\beta$ -modification. Sol. in  $\text{N-H}_2\text{SO}_4$  at ord. temp. Sol. in  $\text{N-NaOH}$  and in hot  $\text{NaOH}$  of concentration  $5\text{Na}_2\text{O}$ ,  $100\text{H}_2\text{O}$ . (Russ, Z. anorg. 1904, 41. 226.)

$\beta$ -modification. Insol. in  $\text{N-H}_2\text{SO}_4$  at ord. temp. Difficultly sol. in warm  $\text{N-NaOH}$ , but easily sol. in hot  $\text{NaOH}$  of concentration  $5\text{Na}_2\text{O}$ ,  $100\text{H}_2\text{O}$ . Its solubility in  $\text{NaOH}$  increases with increase in concentration of the hydroxyl ions. (Russ.)

$\delta$ -modification. Easily sol. in conc.  $\text{H}_2\text{SO}_4$ ; only sl. sol. in  $\text{HCl}$ ,  $\text{HNO}_3$ , or acetic acids, or in alkali +  $\text{Aq.}$  (Tommasi, C. C. 1905, II. 605.)

Min. *Gibbsite*. Sol. in  $\text{HCl} + \text{Aq.}$  and dil.  $\text{H}_2\text{SO}_4 + \text{Aq.}$  Readily sol. in conc.  $\text{KOH}$ , and  $\text{NaOH} + \text{Aq.}$

**Precipitated.** Completely insol. in  $\text{H}_2\text{O}$  or  $\text{H}_2\text{CO}_3 + \text{Aq.}$  Easily sol. in acids when freshly pptd., but solubility diminishes on standing.

Easily sol. in  $\text{KOH}$  or  $\text{NaOH} + \text{Aq.}$  (Sonnenschein.)

Herz (Z. anorg. 25, 155) found that aluminum hydroxide which has been dried in a vacuum dessicator requires for solution in NaOH+Aq. 3 atoms Na to 1 atom Al. Slade (Z. Elektrochem. 1911, 17, 261) was unable to obtain this result. Herz says Slade's error is due to insufficient shaking of the solution. (Herz, Z. Elektrochem. 1911, 17, 403.)

New solubility determinations verify the statement of Herz (Z. anorg. 25, 155) that the solubility of  $\text{Al}(\text{OH})_3$  in  $\text{NaOH}+\text{Aq}$  is proportional to the concentration of NaOH. They do not, however, verify his statement that the ratio Na : Al in the solutions is always 3 : 1, for the author finds that the ratio Na : Al varies from 2 : 1 to 10 : 1 depending on the conditions of precipitation and the method and duration of drying of the  $\text{Al}(\text{OH})_3$ . (Slade, Z. Elektrochem. 1912, 18, 1.)

Sl. sol. in  $\text{NH}_4\text{OH}+\text{Aq}$  when freshly pptd., but presence of  $\text{NH}_4$  salts diminish its solubility, and it separates out completely after long standing. (Fresenius.)

Somewhat sol. in  $\text{NH}_4\text{OH}+\text{Aq}$ , the more readily the larger the vol. of  $\text{H}_2\text{O}$ . Somewhat sol. in  $(\text{NH}_4)_2\text{CO}_3+\text{Aq}$ , but less than in  $\text{NH}_4\text{OH}+\text{Aq}$ . Sl. sol. in dil.  $\text{NH}_4\text{Cl}+\text{Aq}$ , unless that salt be in large excess. It is finally wholly pptd. if allowed to stand several days.

18752 pts.  $\text{NH}_4\text{OH}+\text{Aq}$  (4 %  $\text{NH}_4\text{OH}$ ) dissolve an amt. of  $\text{Al}(\text{OH})_3$  corresponding to one pt.  $\text{Al}_2\text{O}_3$ ;  $\text{NH}_4\text{Cl}$  prevents this solubility almost completely. (Hanamann, Pharm. Viertelj. 12, 527.)

$\text{Al}(\text{OH})_3$ , prepared by ppt. of a solution of  $\text{Al}(\text{NO}_3)_3$  with  $\text{NH}_4\text{OH}$ , filtered and washed, is insol. in  $\text{NH}_4\text{OH}+\text{Aq}$ .

$\text{Al}(\text{OH})_3$  prepared by pptn. of a solution of potassium aluminate with  $\text{NH}_4\text{Cl}$ , is sol. in a large excess of  $\text{NH}_4\text{OH}$  if this is added to the ppt. at once. This modification which is sol. in  $\text{NH}_4\text{OH}$  is unstable and easily goes over into the modification which is insol. in  $\text{NH}_4\text{OH}$ . (Renz, B. 1903, 36, 2751.)

Conc.  $(\text{NH}_4)_2\text{CO}_3+\text{Aq}$  does not dissolve  $\text{Al}(\text{OH})_3$ , and not a trace is dissolved by boiling conc.  $\text{NH}_4\text{Cl}+\text{Aq}$ . (Weeren, Pogg. 92, 97.)

With  $\text{NH}_4\text{F}+\text{Aq}$ , it forms a double salt,  $\text{AlF}_3 \cdot 3\text{NH}_4\text{F}$ , which is sol. in  $\text{H}_2\text{O}$ , but not in  $\text{NH}_4\text{F}+\text{Aq}$ . (Helmholtz, Z. anorg. 3, 127.)

Insol. in  $(\text{NH}_4)_2\text{S}+\text{Aq}$ . (Malaguti and Durocher, A. ch. (3) 17, 421.) Fuchs found, on the contrary, that it is not wholly insol. in  $(\text{NH}_4)_2\text{S}+\text{Aq}$ . (Fresenius, Quant.)

Insol. in  $\text{FeCl}_3+\text{Aq}$ . (Béchamp.) Determinations of the solubility of aluminum hydroxide in  $\text{AlCl}_3+\text{Aq}$  show that part goes into solution to form a compound, while the greater part is in the colloidal form. (Fischer, Z. anorg. 1904, 40, 46.)

Only sl. sol. in conc.  $\text{Al}_2(\text{SO}_4)_3+\text{Aq}$ , but solubility increases with decrease in concentration of  $\text{Al}_2(\text{SO}_4)_3$ , until it reaches a maximum at a concentration of 32 %  $\text{Al}_2(\text{SO}_4)_3$  at 20°, 28 % at 40°, and 38 % at 60°. With further decrease in concentration of  $\text{Al}_2(\text{SO}_4)_3$

the solubility of  $\text{Al}(\text{OH})_3$  in  $\text{Al}_2(\text{SO}_4)_3$  diminishes. (Kremann, C. A. 1909, 2422.)

Sol. in  $\text{Ba}(\text{OH})_2+\text{Aq}$ . (Rose.)

Sol. in boiling  $\text{Fe}(\text{NO}_3)_3$ ,  $\text{Cr}(\text{NO}_3)_3$ ,  $\text{Bi}(\text{NO}_3)_3$ ,  $\text{Hg}(\text{NO}_3)_2$ ,  $\text{HgNO}_3$ ,  $\text{SnCl}_2$ , and  $\text{SbCl}_3+\text{Aq}$ . (Persoz.)

Insol. in  $\text{HCN}$  or cold  $\text{KCN}+\text{Aq}$ ; but sl. sol. in hot  $\text{KCN}+\text{Aq}$ . (Rose.)

Insol. in  $\text{K}_2\text{C}_2\text{H}_3\text{O}_2+\text{Aq}$ . (Osann, 1821.)

When moist, sol. in  $\text{H}_2\text{SO}_4+\text{Aq}$ , from which it is reprecipitated on boiling. (Berthier, A. ch. (3) 7, 76.)

Somewhat sol. in  $\text{NaC}_2\text{H}_3\text{O}_2+\text{Aq}$ . (Mercer.)

Not pptd. by  $\text{NH}_4\text{OH}+\text{Aq}$  in presence of Na citrate. (Spiller.)

$\text{Al}_2\text{O}_4\text{H}_{10}$ , "Trialuminum hydroxide."

Not sol. in conc. acids in the cold; not sol. in  $\text{KOH}$  (cold) and only sl. sol. in hot  $\text{KOH}$ . Characterized by its solubility in exactly one mol. dil.  $\text{HCl}$ . Dil. solutions do not gelatinize even on long standing. Conc. solution of  $\text{NH}_4\text{Cl}$  and other salts cause ppt. which redissolves on addition of  $\text{H}_2\text{O}$ .

Alkalies and alkali carbonates decomp. the salt with  $\text{HCl}$  and ppt. trialuminium hydroxide.  $\text{H}_2\text{SO}_4$  and sol. sulphates give insol. compds. with the hydrate.  $\text{HNO}_3$  like  $\text{HCl}$  gives soluble compds. with the hydrate. (Structural formula given.) (Schlumberger, Bull. Soc. 1895, (5) 13, 41-65; C. C. 1895, I, 421.)

(Roscoe and Dittmar, A. 112. 349.)

In proportion as the temperature is higher, so much the more nearly does the solubility of  $\text{NH}_3$  in  $\text{H}_2\text{O}$  conform to the law of Henry and Dalton, but only obeys it completely when the temperature is  $100^\circ$ , as is seen in the following table.

Solubility of  $\text{NH}_3$  in  $\text{H}_2\text{O}$  at various pressures and temperatures: P=partial pressure, i. e. total pressure minus the tension of aqueous vapour at the given temperature; G=grams  $\text{NH}_3$  dissolved in 1 g.  $\text{H}_2\text{O}$  at the given pressure; G at 760=grams  $\text{NH}_3$  that would be contained in 1 g.  $\text{H}_2\text{O}$  if the solubility was proportional to the pressure.

100 pts. sat. KOH + Aq dissolve only 1 pt.  $\text{NH}_3$ .

Solubility in NaOH + Aq is the same as in KOH + Aq of the same strength.

$\text{NH}_4\text{Cl}$  + Aq absorbs slightly less  $\text{NH}_3$  than the same vol.  $\text{H}_2\text{O}$ .  $\text{NaNO}_3$ , and  $\text{NH}_4\text{NO}_3$  + Aq absorb almost the same amount  $\text{NH}_3$  as the same vol.  $\text{H}_2\text{O}$ . (Raoult, *l.c.*)

The solubility of  $\text{NH}_3$  in  $\text{NaNO}_3$ ,  $\text{NH}_4\text{NO}_3$  and in  $\text{AgNO}_3$ ,  $2\text{NH}_3$  + Aq is nearly the same as in pure  $\text{H}_2\text{O}$ . (Konowaloff, C. C. 1898, II. 659).

Distribution-coefficient of  $\text{NH}_3$  between water and  $\text{CHCl}_3$  = 26.3 at 20°; 24.9 at 25°; 23.2 at 30°.

Sat.  $\text{NH}_4\text{Cl}$  + Aq boils at  $115.8^{\circ}$  at 718 mm. pressure. (Alluard, C. R. **59**, 500.)

$\text{NH}_4\text{Cl}$  + Aq containing 74.2 pts.  $\text{NH}_4\text{Cl}$  to 100 pts.  $\text{H}_2\text{O}$  forms a crust at  $113^{\circ}$ ; highest temperature observed,  $114.8^{\circ}$ . (Gerlach, Z. anal. **26**, 426.)

$\text{NH}_4\text{Cl}$  + Aq containing 10%  $\text{NH}_4\text{Cl}$  boils at  $101.7^{\circ}$ ; 20%  $\text{NH}_4\text{Cl}$  at  $104.4^{\circ}$ . (Gerlach.)

$\text{NH}_4\text{Cl}$  + Aq containing 10.6%  $\text{NH}_4\text{Cl}$  gives off  $\text{NH}_3$  at  $37^{\circ}$ . (Leeds, Am. J. Sci. (3) **7**, 197.)

When  $\text{NH}_4\text{Cl}$  + Aq is boiled, or even evap. on water bath, a little  $\text{NH}_3$  is expelled. (Fresenius.)

30 pts.  $\text{NH}_4\text{Cl}$  mixed with 100 pts.  $\text{H}_2\text{O}$  lower the temp. from  $13.3^{\circ}$  to  $-5.1^{\circ}$ , that is  $18.4^{\circ}$ . (Rüdorff, B. **2**, 68.)

Freezing-point of sat. solution is  $-15.4^{\circ}$ , the same temp. which is caused by mixing 25 pts.  $\text{NH}_4\text{Cl}$  with 100 pts. snow. (Rüdorff, Pogg. **122**, 337.)

Conc.  $\text{HCl}$  + Aq precipitates part of  $\text{NH}_4\text{Cl}$  from sat.  $\text{NH}_4\text{Cl}$  + Aq. (Vogel, J. pr. **2**, 199.)

### Antimony, Sb.

Does not decomp. H<sub>2</sub>O. Not attacked by HCl+Aq (Berzelius); slowly sol. in conc. HCl+Aq (Debray); slowly sol. in conc. warm HCl+Aq (Troost). Attacked by very conc. HCl+Aq only when finely divided (Schützenberger, Willm); very sl. attacked by dil. or conc. acid (Guntz). Not attacked by boiling HCl+Aq (Gmelin). By careful experiments, pure Sb is absolutely insol. in dil. or conc., hot or cold HCl+Aq, except when in contact with oxygen. (Ditte and Metzner, *A. ch.* (6) 29. 889.)

Insol. in dil. or cold conc., but sol. in hot conc. H<sub>2</sub>SO<sub>4</sub>. Oxidized but not dissolved by HNO<sub>3</sub>+Aq. Easily and completely sol. in aqua regia.

Very slowly attacked by pure HNO<sub>3</sub>+Aq of 1.51-1.42 sp. gr.; weaker acid has no marked action whether it contains NO<sub>2</sub> or not. HCl+HNO<sub>3</sub> has no action if dil. or at low temp., but when even very dil. and KNO<sub>2</sub> is added, the action will begin. (Millon, *A. ch.* (3) 6. 101.)

Not attacked in 10 months by 2% HNO<sub>3</sub>+Aq. Sb is not dissolved by HNO<sub>3</sub>+Aq of any concentration, a white powder being always left, which is insol. in HNO<sub>3</sub>+Aq or H<sub>2</sub>O. (Montemartini, *Gazz. ch. it.* 22. 384.)

Alkaline H<sub>2</sub>O<sub>2</sub> converts Sb into antimonic acid, but neutral H<sub>2</sub>O<sub>2</sub> is without action. (Clark, *Chem. Soc.* 1893, 63. 886.)

Insol. in liquid NH<sub>3</sub>. (Gore, *Am. Ch. J.* 1898, 20. 826.)

Easily attacked by pyrosulphuryl chloride. (Heumann and Köchlin, B. 16. 479.)

$\frac{1}{2}$  cc. oleic acid dissolves 0.0007 g. Sb in 6 days. (Gates, J. phys. Ch. 1911, 15. 143.)

There are three modifications:

1. Ordinary gray metallic.

2. Black amorphous. Unstable at ord. temp. By boiling with  $\text{H}_2\text{O}$  is changed to metallic Sb.

3. Yellow. Very unstable. At  $-50^\circ$  goes over rapidly into the ordinary black modification. Sol. in  $\text{CS}_2$  at a little above  $-90^\circ$ . (Stock, B. 1903, 37. 898.)

Unstable above  $-90^\circ$ . (Stock, B. 1905, 38. 3837.)

**Arsenic trioxide,  $\text{As}_2\text{O}_3$ .**

"White arsenic" exists in two modifications:  $\alpha\text{As}_2\text{O}_3$ ,—crystalline, octahedral, opaque, porcelainous, etc.;  $\beta\text{As}_2\text{O}_3$ ,—amorphous, vitreous, "arsenic glass."

The data concerning the solubility of  $\text{As}_2\text{O}_3$  are very contradictory, the reasons being that (1) the solubility of the two modifications is different; (2) that the length of time necessary to effect solution differs in the two modifications; and (3) that there is a tendency of the amorphous  $\text{As}_2\text{O}_3$  to go over into the crystalline state during the process of solution.  $\alpha\text{As}_2\text{O}_3$  is also not easily moistened, especially when in a pulverulent condition, which is not the case with the  $\beta$  modification. (Winkler, J. pr. (2) 31. 247.)

The older data are very unreliable, but possess a certain historical interest.

1 pt.  $\text{As}_2\text{O}_3$  is sol. in 10.55 pts. (Wenzel); 11.34 pts. (Fischer); 11.86 pts. in  $\frac{1}{4}$  hour (Klaproth); 12.2 pts. (Bucholz); 15.0 pts. (Brandt; Bergman); 16.0 pts. (Vogel); 24 pts. (Lametherie); 40 pts. (Förner); 64 pts.

(Baumé); 80 pts. (Navier); 200 pts. (Aschof and Nasse, 1812); 640 pts. (Hagen, 1796) boiling  $\text{H}_2\text{O}$ .

1 pt.  $\text{As}_2\text{O}_3$  is sol. in 7.72 pts.  $\text{H}_2\text{O}$  if  $\alpha$ , or 9.33 pts. if  $\beta$  (Guibort); in 24 pts.  $\text{H}_2\text{O}$  if  $\alpha$ , or 21 pts. if  $\beta$  (Taylor).

Sol. in 53.3 pts.  $\text{H}_2\text{O}$  at  $18.75^\circ$ . (Abl.)

Sol. in 30 pts.  $\text{H}_2\text{O}$ . (Nussebrock.)

After the solution in  $\text{H}_2\text{O}$  at  $100^\circ$  has been left standing at ordinary temperatures—

1 pt.  $\text{As}_2\text{O}_3$  remains dissolved in 16 pts.  $\text{H}_2\text{O}$  at  $16^\circ$  and 20 pts.  $\text{H}_2\text{O}$  at  $7^\circ$  (Bucholz); in 33 pts.  $\text{H}_2\text{O}$  at  $7^\circ$  (Klaproth); in 38.45 pts.  $\text{H}_2\text{O}$  after 3 days, 55 pts.  $\text{H}_2\text{O}$  after 8 days; 54.50 pts.  $\text{H}_2\text{O}$  after 2.3 weeks at  $10^\circ$  (Fischer); in 33.52 pts. if  $\alpha\text{As}_2\text{O}_3$  was used, 55.06 pts. if  $\beta\text{As}_2\text{O}_3$  was used (Guibort); in 38 pts. if  $\alpha\text{As}_2\text{O}_3$  after 6 months, 53.71 pts. if  $\beta\text{As}_2\text{O}_3$  after 48 hours (Taylor).

When an excess of pulverized  $\text{As}_2\text{O}_3$  is left to digest for several days with cold  $\text{H}_2\text{O}$ —

1 pt. dissolves in 50 pts. (Bucholz); in 66 pts. (Fischer); in 80 pts. at  $15^\circ$  (Bergman); in 80 pts. if  $\alpha$ , and 103 pts. if  $\beta$  (Guibort); 96 pts. at  $10^\circ$  (Spielman); 96 pts. at  $35.5^\circ$  (Hahnemann); 320 pts.  $\text{H}_2\text{O}$  at  $20^\circ$  (Aschof and Nasse, 1812.)

$\text{H}_2\text{O}$  at  $15.6^\circ$  or below dissolves less than  $\frac{1}{4}\%$   $\text{As}_2\text{O}_3$ . (Dalton.)

To dissolve 1 pt.  $\text{As}_2\text{O}_3$  in 12 pts.  $\text{H}_2\text{O}$ , it is necessary to boil an excess of  $\text{As}_2\text{O}_3$  with  $\text{H}_2\text{O}$ ; if 1 pt.  $\text{As}_2\text{O}_3$  is boiled with 12 pts.  $\text{H}_2\text{O}$ , considerable remains undissolved; and even with 1 pt.  $\text{As}_2\text{O}_3$  to 50–60 pts.  $\text{H}_2\text{O}$  long continued boiling is necessary to effect solution. If a clear solution saturated by long boiling with an excess of  $\text{As}_2\text{O}_3$  is poured off and evaporated continuously to  $\frac{1}{2}$  its original bulk, no  $\text{As}_2\text{O}_3$  separates out, and the solution contains 1 pt.  $\text{As}_2\text{O}_3$  to 6 pts.  $\text{H}_2\text{O}$ . (Fischer.)

100 pts. aqueous solution of  $\beta\text{As}_2\text{O}_3$  sat. at  $15^\circ$  contain 0.96 pt.  $\text{As}_2\text{O}_3$ , and 9.68 pts. when sat. at  $100^\circ$ . (Guibort.)

If 1 pt. pulverized  $\text{As}_2\text{O}_3$  be digested 10 days at  $19\text{--}25^\circ$  in 5–10 pts.  $\text{H}_2\text{O}$ , the solution contains 1 pt.  $\text{As}_2\text{O}_3$  to 50 pts.  $\text{H}_2\text{O}$ . A solution of same strength is obtained in 25 days by digesting 1 pt.  $\text{As}_2\text{O}_3$  in 40 pts.  $\text{H}_2\text{O}$ . If 1 pt.  $\text{As}_2\text{O}_3$  be immersed in 80 pts.  $\text{H}_2\text{O}$ , the resulting solution contains 1 pt.  $\text{As}_2\text{O}_3$  to 90 pts.  $\text{H}_2\text{O}$ ; if in 160 pts.  $\text{H}_2\text{O}$ , 1 pt.  $\text{As}_2\text{O}_3$  to 180 pts.  $\text{H}_2\text{O}$ ; if in 240 pts.  $\text{H}_2\text{O}$ , 1 pt.  $\text{As}_2\text{O}_3$  to 280 pts.  $\text{H}_2\text{O}$ ; if in 1000 pts.  $\text{H}_2\text{O}$ , 1 pt.  $\text{As}_2\text{O}_3$  to 1200 pts.  $\text{H}_2\text{O}$ ; and even when 1 pt.  $\text{As}_2\text{O}_3$  is digested at ordinary temperatures for several days with 16,000–100,000 pts.  $\text{H}_2\text{O}$ , a portion remains undissolved. Pulverized  $\alpha\text{As}_2\text{O}_3$  was set aside with  $\text{H}_2\text{O}$  in closed bottles for 18 years; when 1 pt.  $\text{As}_2\text{O}_3$  was present in 1000 pts.  $\text{H}_2\text{O}$ , a perfect solution was obtained; when 1 pt.  $\text{As}_2\text{O}_3$  in 100 pts.  $\text{H}_2\text{O}$ , 0.017%  $\text{As}_2\text{O}_3$  was undissolved; when 1 pt.  $\text{As}_2\text{O}_3$  in 35 pts.  $\text{H}_2\text{O}$ , 0.35%  $\text{As}_2\text{O}_3$  was undissolved, so that the solution contained 1 pt.  $\text{As}_2\text{O}_3$  to 54 pts.  $\text{H}_2\text{O}$ . (Gmelin.)

Porcelainous modification ( $\alpha\text{As}_2\text{O}_3$ ) is much more sol. in  $\text{H}_2\text{O}$  than the vitreous ( $\beta\text{As}_2\text{O}_3$ ). 100 pts.  $\text{H}_2\text{O}$  at ordinary temperature dissolve 0.96 pt.  $\beta\text{As}_2\text{O}_3$  and 1.25 pts.  $\alpha\text{As}_2\text{O}_3$ ; 100 pts. boiling  $\text{H}_2\text{O}$  dissolve 9.68 pts.  $\beta\text{As}_2\text{O}_3$  and 11.47 pts.  $\alpha\text{As}_2\text{O}_3$ ; and when the temperature of this solution has fallen to  $15^\circ$ , the solution from  $\beta\text{As}_2\text{O}_3$  retains 1.78 pts., and that from  $\alpha\text{As}_2\text{O}_3$  retains 2.9 pts. (Berzelius [citing Guibort].)

$\beta\text{As}_2\text{O}_3$  dissolves more quickly and abundantly than  $\alpha\text{As}_2\text{O}_3$ . The same amount  $\text{H}_2\text{O}$  which will take up 36–38 pts.  $\beta\text{As}_2\text{O}_3$  at  $12\text{--}13^\circ$  will dissolve only 12–14 pts.  $\alpha\text{As}_2\text{O}_3$ , or 100 pts.  $\text{H}_2\text{O}$  dissolve 4 pts.  $\beta\text{As}_2\text{O}_3$  and 1.2–1.3 pts.  $\alpha\text{As}_2\text{O}_3$ . By long boiling with  $\text{H}_2\text{O}$ ,  $\alpha\text{As}_2\text{O}_3$  is converted into  $\beta\text{As}_2\text{O}_3$ , and thus acquires the solubility of the latter, so that 100 pts. boiling  $\text{H}_2\text{O}$  can take up 11 pts.  $\text{As}_2\text{O}_3$ . But at low temperature  $\beta\text{As}_2\text{O}_3$  is converted into  $\alpha\text{As}_2\text{O}_3$  when in contact with  $\text{H}_2\text{O}$ , so that the solution becomes weaker after a while, and retains only the proportion of  $\text{As}_2\text{O}_3$  corresponding to the solubility of  $\alpha\text{As}_2\text{O}_3$ . Communion, which hastens the rate of solubility of  $\alpha\text{As}_2\text{O}_3$ , without increasing the amount dissolved, diminishes the solubility of  $\beta\text{As}_2\text{O}_3$ , as this is converted into  $\alpha\text{As}_2\text{O}_3$ .

Easily sol. in  $\text{NH}_4$  arsenite + Aq at  $70-80^\circ$ , crystallizing out on cooling. (Berzelius.)

When 1 pt. powdered  $\text{As}_2\text{O}_3$  is digested 30 days in 10-40 pts. alcohol, a solution is formed containing 1 pt.  $\text{As}_2\text{O}_3$  to 60 pts. alcohol; when 1 pt.  $\text{As}_2\text{O}_3$  is digested with 60-150 pts. alcohol, a solution is formed containing 1 pt.  $\text{As}_2\text{O}_3$  to 124-140 pts. alcohol. (Fischer.)

Sol. in 70-80 pts. alcohol. (Thompson.)

Alcohol dissolves 0.446 pt.  $\beta\text{As}_2\text{O}_3$ . (Rose, A. Phys. (1) 52. 455.)

Borates.

No borate is quite insol. in H<sub>2</sub>O; the alkali borates are very sol. The less sol. borates are easily decomp. by H<sub>2</sub>O; the easily sol. salts are also decomp., but less quickly. The less sol. borates are easily sol. in H<sub>2</sub>BO<sub>3</sub>, HNO<sub>3</sub>, etc. They are more sol. in H<sub>2</sub>O containing tartaric acid or potassium tartrate than in pure H<sub>2</sub>O. (Souberain.) The normal borates of the alkaline-earths are sol. to no inconsiderable extent in H<sub>2</sub>O, and more readily in hot, than in cold H<sub>2</sub>O. (Berzelius, Pogg. 34. 568.)

All borates are insol., or sl. sol. in alcohol.

Much more sol. in  $HCl + Aq$  than in  $H_2O$ . 100 cc.  $HCl + Aq$  of 1.153 sp. gr. dissolve 36.4 g.  $Br$  at  $12^\circ$ .

More sol. in  $SrCl_2$ , and  $BaCl_2 + Aq$  than in  $H_2O$ . (Berthelot, C. R. 100. 761.)

Bromine is not more sol. in KBr+Aq than in H<sub>2</sub>O (?). (Balard.)

KBr+Aq containing 1 pt. KBr to 6 pts. H<sub>2</sub>O takes up as much Br as it already contains; when this solution is heated the dissolved Br is separated. 1 pt. KBr+1 pt. H<sub>2</sub>O takes up twice as much Br as it already contains, much heat being evolved. This solution loses Br on exposure to the air or when heated. (Löwig.)

Solutions of salts of the following concentration cause an immediate coagulation in an aqueous solution of  $CdS$  containing 3.62 g. in a litre.
